## Outline

- Bayesian networks
- Inference with Lazy Propagation
- Inference with Simple Propagation
- Experimental Results \& Analysis
- Conclusions

## BayEsian Networks

A Bayesian Network (BN) consists of:

- a directed acyclic graph (DAG)
- a matching set of conditional probability tables (CPTs)

The product of the CPTs is a join probability distribution (JPD) $P(U)$

## Bayesian Network Example

m
$P(U)=P(a) \cdot P(b \mid a) \cdot P(c \mid a) \cdot P(d \mid b, c) \cdot \ldots \cdot P(m \mid g, l)$

## LAZY PROPAGATION

- Madsen and Jensen (AIJ 1999)
- BN variables are clustered into nodes
- Nodes are organized as a join tree
- Each BN CPT is assigned to a join tree node
- Messages are propagated systematically

## Message Construction

$$
\begin{gathered}
\text { message }=\sum_{N-N^{\prime}} \text { Factorization at } N \\
M=\sum_{b, c, e, f, g, h} P(b, c) \cdot P(d=0 \mid b, c) \cdot P(e \mid d=0) \cdot P(f \mid d=0, e) \\
\quad P(g \mid e) \cdot P(h \mid e) \cdot P(i \mid d=0, h) \cdot P(j \mid i) \cdot P(m \mid g, l)
\end{gathered}
$$

## Detecting Irrelevant Potentials

- LP constructs:
- the domain graph $\mathrm{G}_{1}$ of the factorization
- the moralization $G_{1}{ }^{m}$ of $G_{1}$
- LP tests whether the evidence separates the variables to be marginalized from the separator
- if separated, the potential is irrelevant

## Build Domain Graph $\mathrm{G}_{1}$

## Build Moralization Graph $\mathrm{G}_{1}{ }^{m}$

## Test Independence for Each Potential

- For $P(b, c)$, test whether evidence $d$ separates $b$ and $c$ from the separator $S=\{i, j, I, m\}$

- Thus, $P(b, c)$ is irrelevant

## DETERMINING Elimination Orderings

- LP constructs:
- the domain graph $\mathrm{G}_{2}$ of the relevant potentials
- the moralization $\mathrm{G}_{2} \mathrm{~m}$ of $\mathrm{G}_{2}$
- obtain an elimination ordering from $\mathrm{G}_{2}{ }^{m}$

## Build Domain Graph $\mathrm{G}_{2}$

$$
\mathcal{F}=\{P(e \mid d=0), P(g \mid e), P(h \mid e), P(i \mid d=0, h), P(j \mid i), P(m \mid g, l)\}
$$

## Build Moralization Graph G2m

## Find Elimination Ordering

- elimination ordering: $g, e, h$

## Now LP Can Build the Message

$$
\begin{align*}
M & =\sum_{e, g, h} P(e \mid d=0) \cdot P(g \mid e) \cdot P(h \mid e) \cdot P(i \mid d=0, h) \cdot P(j \mid i) \cdot P(m \mid g, l) \\
& =P(j \mid i) \cdot \sum_{h} P(i \mid d=0, h) \cdot \sum_{e} P(e \mid d=0) \cdot P(h \mid e) \cdot \sum_{g} P(g \mid e) \cdot P(m \mid g, l) \\
& =P(j \mid i) \cdot P(i, m \mid d=0, l) \tag{1}
\end{align*}
$$

## SIMPLE PROPAGATION

## Darwinian Networks

- Simple Propagation arose from our work on Darwinian Networks (Al 2015)
- clever way to view CPTS

$$
P(g \mid e, f)
$$

## Multiplication is Merge

owhite + - black $=$ owhite<br>- black + owhite $=$ owhite<br>- black + - black $=$ - black owhite + owhite $=$ - black

# Marginalization is <br> Replication and Natural Selection 

Replication
Natural selection

$$
\sum_{c} P(c, e \mid d, h)=P(e \mid d, h)
$$

## Simple Propagation

SP only uses the "one in, one out" property:
a potential with one non-evidence variable in the separator and another not in the separator

## Simple Propagation

Evidence is $d=0$

Variable $\boldsymbol{g}$ is outside of $S$ and variables / and $m$ are in $S$

## Simple Propagation

Eliminating variable $g$ yields population $p(m \mid e, I)$

## Simple Propagation

Now, variable $\boldsymbol{e}$ is out

## Simple Propagation

Eliminating variable e yields $p(h, m \mid d=0, I)$

## Simple Propagation

Finally, variable $\boldsymbol{h}$ is out

## Simple Propagation

Eliminating variable $h$ yields population $p(i, m \mid d=0, I)$

- Experiments conducted on optimal JTs built from realworld and benchmark BNs
- SP was faster in $18 / 28$
- SP tied LP in $5 / 28$
- LP was faster in 5/28

## LP ANALYSIS

- Left-to-Right viewpoint

## SP ANALYSIS

- Right-to-Left viewpoint

## SP ANALYSIS

- Right-to-Left viewpoint

## EXPERIMENTAL RESULTS

## SP Heuristics

- SP is a new BN inference algorithm
- There may be more than one potential satisfying the "one in, one out" property

## SP Heuristics

- Increasing variables in $X(\operatorname{Inc} X)$
- Decreasing variables in $X(\operatorname{Dec} X)$
- Increasing variables of $X$ in $S$ (Inc in S)
- Decreasing variables of $X$ in $S($ Dec in $S$ )
- Increasing variables in X size (Inc X Size)
- Decreasing variables in X size (Dec X Size)
- Increasing variables of $X$ in $S$ size (Inc in $S$ Size)
- Decreasing variables of $X$ in $S$ size (Dec in $S$ Size).

## ANALYSIS

- Our experimental results suggest that SP does not require elimination orderings, provided that an optimal (or close to) join tree is built from the realworld BNs
- It is possible that elimination orderings are needed for larger BNs or when non-optimal join trees are used, since SP's performance degrades dramatically when applied on non-optimal join trees (Madsen et al., 2016 Canadian AI)

## Conclusion

- SP is a new BN inference algorithm
- "one in, one out" property
- SP is faster than LP in optimal join trees
- Our heuristics were slower than choosing potentials arbitrarily
